

Random Generators of Given Orders and the Smallest Simple Moufang Loop

PETR VOJTĚCHOVSKÝ

ABSTRACT. The probability that m randomly chosen elements of a finite power associative loop C have prescribed orders and generate C is calculated in terms of certain constants Γ related to the action of $\text{Aut}(C)$ on the subloop lattice of C . As an illustration, all meaningful probabilities of random generation by elements of given orders are found for the smallest nonassociative simple Moufang loop.

1. Random generators of given orders

Let C be a power associative loop, i.e., a loop where every element generates a group. Given an m -tuple $\mathbf{a} = (a_0, \dots, a_{m-1})$ of elements of C , let $\mathbf{A} = \{A_i\}_{i=0}^m$ be the sequence of nested subloops $A_i \leq C$ such that A_0 is the smallest subloop of C , and $A_{i+1} = \langle A_i, a_i \rangle$. Note that A_m is independent of the order of the elements $a_0, \dots, a_{m-1}$ in $\mathbf{a}$.

Denote by $\text{Gen}_m(C)$ the set of all m -tuples $\mathbf{a} \in C^m$ with $A_m = C$. Then the probability that m randomly chosen elements of C generate C is

$$p_m(C) = |C|^{-m} \cdot |\text{Gen}_m(C)|. \quad (1)$$

This notion can be refined in a natural way. For $1 \leq i \leq n$, let D_i be the set of all elements of C of order i . Two m -tuples of integers $\mathbf{r} = (r_0, \dots, r_{m-1})$, $\mathbf{s} = (s_0, \dots, s_{m-1})$ are said to be of *the same type* if $r_0, \dots, r_{m-1}$ is a permutation of $s_0, \dots, s_{m-1}$. We say that $\mathbf{a} = (a_0, \dots, a_{m-1}) \in C^m$ is of *type* $\mathbf{r}$ if there is $\mathbf{s} = (s_0, \dots, s_{m-1})$ of the same type as $\mathbf{r}$ satisfying $a_i \in D_{s_i}$, for $0 \leq i \leq m-1$.

Let $\text{Gen}_{\mathbf{r}}(C) \subseteq \text{Gen}_m(C)$ be the set of generating m -tuples of type $\mathbf{r}$. Then

$$p_{\mathbf{r}}(C) = |C|^{-m} \cdot |\text{Gen}_{\mathbf{r}}(C)| \quad (2)$$

is the probability that m randomly chosen elements $a_0, \dots, a_{m-1} \in C$ generate C and $(a_0, \dots, a_{m-1})$ is of type $\mathbf{r}$.

For $A, B \leq C$ and an integer i , let $\Gamma_i(A, B)$ be the cardinality of the set of all elements $x \in D_i$ such that $\langle A, x \rangle \in O_B$, where O_B is the orbit of B under the natural action of $\text{Aut}(C)$ on the subloop lattice of C . Also, let $\Gamma(A, B)$ be the cardinality of the set of all elements $x \in C$ such that $\langle A, x \rangle \in O_B$.

Key words and phrases: random generators of given orders, Moufang loops, Paige loops.

While working on this paper the author has been partially supported by Grant Agency of Charles University, grant number 269/2001/B-MAT/MFF.

We are going to divide C^m into certain equivalence classes. Two m -tuples $\mathbf{a}, \mathbf{b} \in C^m$ with associated nested subloops $\{A_i\}_{i=0}^m, \{B_i\}_{i=0}^m$ will be called *orbit-equivalent* if $A_i \in O_{B_i}$, for $0 \leq i \leq m$. We write $\mathbf{a} \sim \mathbf{b}$.

The size of the equivalence class $\mathbf{a}_\sim$ is easy to calculate with help of the constants $\Gamma(A, B)$. There are $\Gamma(A_0, A_1)$ elements x such that $\langle A_0, x \rangle \in O_{A_1}$. Once we are in the orbit O_{A_i} , we can continue on the way to $O_{A_{i+1}}$ by adding one of the $\Gamma(A_i, A_{i+1})$ elements x_{i+1} to $\langle x_0, \dots, x_i \rangle$. Thus,

$$|\mathbf{a}_\sim| = \prod_{i=0}^{m-1} \Gamma(A_i, A_{i+1}). \quad (3)$$

Since

$$|\text{Gen}_m(C)| = \sum_{\mathbf{a}_\sim \in \text{Gen}_m(C)/\sim} |\mathbf{a}_\sim|, \quad (4)$$

we can combine (1), (3) and (4) to obtain

$$p_m(C) = |C|^{-m} \sum_{\mathbf{a}_\sim \in \text{Gen}_m(C)/\sim} \prod_{i=0}^{m-1} \Gamma(A_i, A_{i+1}). \quad (5)$$

Example 1.1. Let us illustrate (5) by calculating the probability that two randomly chosen elements of S_3 generate the entire symmetric group. Let e be the neutral element of S_3 . There are 3 subgroups isomorphic to C_2 (all in one orbit of transitivity) and a unique subgroup isomorphic to C_3 . As $\Gamma(e, C_2) = 3$, $\Gamma(e, C_3) = 2$, $\Gamma(C_2, S_3) = 4$ and $\Gamma(C_3, S_3) = 3$, we have $p_2(S_3) = (3 \cdot 4 + 2 \cdot 3)/36 = 1/2$, as expected.

Write $\sim_{\mathbf{r}}$ for the restriction of $\sim$ onto $\text{Gen}_{\mathbf{r}}(C)$, and observe that

$$|\mathbf{a}_{\sim_{\mathbf{r}}}| = \sum_{\mathbf{s}=(s_0, \dots, s_{m-1})} \prod_{i=0}^{m-1} \Gamma_{s_i}(A_i, A_{i+1}), \quad (6)$$

where the summation runs over all m -tuples $\mathbf{s}$ of the same type as $\mathbf{r}$. Consequently,

$$p_{\mathbf{r}}(C) = |C|^{-m} \sum_{\mathbf{a}_{\sim_{\mathbf{r}}} \in \text{Gen}_{\mathbf{r}}(C)/\sim_{\mathbf{r}}} \sum_{\mathbf{s}=(s_0, \dots, s_{m-1})} \prod_{i=0}^{m-1} \Gamma_{s_i}(A_i, A_{i+1}). \quad (7)$$

Remark 1.2. All concepts of this section can be generalized to any finite universal algebra C with subsets D_i closed under the action of $\text{Aut}(C)$.

2. Random generators of given orders for $M^*(2)$

We assume from now on that the reader is familiar with the notation and terminology of [2].

The value of $\Gamma_i(A, B)$ in (7) can be calculated with help of Hasse constants, provided A is maximal in B . Namely,

$$\Gamma_i(A, B) = \mathcal{H}_C^*(A|B) \cdot |D_i \cap (B \setminus A)|. \quad (8)$$

This is obvious because $\mathcal{H}_C^*(A|B)$ counts the number of subloops of C containing A and in the same orbit as B .

By (7) and (8), we should be able to calculate $p_m(C)$, $p_r(C)$ when all Hasse constants for C are known and when the lattice of subloops of C is not too high. These probabilities can be used alongside order statistics to recognize black box loops, for instance (cf. [1]).

Building on the results of [2] substantially, we proceed to calculate all meaningful probabilities $p_m(C)$, $p_r(C)$ for $C = M^*(2)$ —the smallest nonassociative simple Moufang loop.

All Hasse constants for C are summarized in [2, Fig. 1], so we can easily evaluate all constants $\Gamma_i(A, B)$ with A maximal in B . For example, since $\mathcal{H}_C^*(E_8|M(A_4)) = 3$ and $|D_2 \cap (M(A_4) \setminus E_8)| = 8$, we have $\Gamma_2(E_8, M(A_4)) = 24$.

Apart from trivialities, the remaining constants to be calculated are

$$\begin{aligned} &\Gamma_i(C_2, A_4), \quad \Gamma_i(S_3, C), \quad \Gamma_i(A_4, C), \quad \Gamma_i(E_4^-, C), \\ &\Gamma_i(E_4^-, M(A_4)), \quad \Gamma_i(E_4^+, M(A_4)), \quad \Gamma_i(E_4^+, C), \quad \Gamma_i(E_8, C), \end{aligned}$$

for $i = 2, 3$. As some invention is needed here, we show how to obtain all of them.

We begin with $\Gamma_i(S_3, C)$. Let G be a copy of S_3 in C . For any element $x \notin G$, we must have $\langle G, x \rangle \cong M(S_3)$, $M(A_4)$, or C . Therefore, $\Gamma_i(S_3, C) = (i-1) \cdot \mathcal{H}_C(C_i) - \Gamma_i(S_3, M(S_3)) - \Gamma_i(S_3, M(A_4)) - (i-1) \cdot \mathcal{H}_{S_3}(C_i)$, for $i = 2, 3$. Consequently,

$$\Gamma_2(S_3, C) = 63 - 6 - 36 - 3 = 18, \quad \Gamma_3(S_3, C) = 56 - 0 - 18 - 2 = 36.$$

Similarly,

$$\begin{aligned} \Gamma_2(C_2, A_4) &= 0, & \Gamma_3(C_2, A_4) &= 24, \\ \Gamma_2(A_4, C) &= 48, & \Gamma_3(A_4, C) &= 48, \\ \Gamma_2(E_8, C) &= 32, & \Gamma_3(E_8, C) &= 32. \end{aligned}$$

A more detailed analysis of the subloop lattice of C allows us to calculate the remaining eight constants.

Lemma 2.1. *Let $G \in O^-$, and let M_1, M_2, M_3 be the three copies of $M(A_4)$ containing G . Then $M_i \cap M_j$ contains no element of order 3, for $i \neq j$, and $M_1 \cap M_2 \cap M_3$ is the unique copy of E_8 containing G . In particular,*

$$\Gamma_3(E_4^-, M(A_4)) = 24, \quad \Gamma_3(E_4^-, C) = 24, \quad \Gamma_2(E_4^-, M(A_4)) = 24, \quad \Gamma_2(E_4^-, C) = 8.$$

Proof. Assume there is $x \in M_i \cap M_j$, $|x| = 3$, for some $i \neq j$. Then $M_i = \langle G, x \rangle = M_j$, because $\mathcal{H}_C(E_4^-|A_4) = 0$, a contradiction. Thus $M_1 \cup M_2 \cup M_3$ contains $3 \cdot 8 = 24$ elements x of order 3 such that $\langle G, x \rangle \in O_{M(A_4)}$.

Let H be the unique copy of E_8 containing G . We must have $H = M_1 \cap M_2 \cap M_3$, since $\mathcal{H}_C(E_8|M(A_4)) = 3$. Therefore $M_1 \cup M_2 \cup M_3$ contains $3 \cdot (12 - 4) = 24$ involutions x such that $\langle G, x \rangle \in O_{M(A_4)}$. The constants $\Gamma_i(E_4^-, C)$ are then easy to calculate with help of Figure 1. $\square$

It is conceivable that there is $G \in O^+$ and $x \in C$ such that $\langle G, x \rangle = C$. It is not so, though.

Lemma 2.2. *In C , we have*

$$\Gamma_3(E_4^+, M(A_4)) = 48, \quad \Gamma_2(E_4^+, M(A_4)) = 48, \quad \Gamma_3(E_4^+, C) = 0, \quad \Gamma_2(E_4^+, C) = 0.$$

Proof. Pick $G \in O^+$, and let $M_1, \dots, M_7$ be the seven copies of $M(A_4)$ containing G . We claim that $(M_i \cap M_j)^2 = e$, for $i \neq j$. Assume it is not true, and let x be an element of order 3 contained in $M_i \cap M_j$. Then $A_4 \cong \langle G, x \rangle \leq M_i \cap M_j$ shows that $\mathcal{H}_{M(A_4)}(A_4) \geq 2$, a contradiction. Thus $\bigcup_{i=1}^7 M_i$ contains all $8 \cdot 7 = 56$ elements of order 3. In particular, we have $\langle G, x \rangle \neq C$ for any element x of order 3. This translates into

$$\Gamma_3(E_4^+, C) = 0, \quad \Gamma_3(E_4^+, M(A_4)) = 56 - \Gamma_3(E_4^+, A_4) = 48.$$

We proceed carefully to show that $\Gamma_2(E_4^+, C) = 0$. The group G is contained in a single copy A of A_4 , that is in turn contained in a single copy M_1 of $M(A_4)$. Let $H_1, H_2, H_3 \leq M_1$ be the three copies of E_8 containing G (see the proof of Lemma 13.1 [2]). Observe that $H_1 \cup H_2 \cup H_3 = G \cup Au$, where Au is the second coset of A in M_1 . Pick M_i, M_j , with $2 \leq i < j \leq 7$. We want to show that $M_i \cap M_j \subseteq M_1$. Thanks to the first part of this Lemma, we know that $M_i \cap M_j \cong E_4$ or E_8 . When $M_i \cap M_j \cong E_4$ then, trivially, $M_i \cap M_j = G \leq M_1$. When $M_i \cap M_j \cong E_8$ then $M_i \cap M_j = H_k$ for some $k \in \{1, 2, 3\}$, else $\mathcal{H}_C(G|E_8) \geq 4$, a contradiction.

Consequently, $\bigcup_{i=1}^7 M_i$ contains at least $15 + 6 \cdot 8 = 63$ involutions; 15 in M_1 , and additional 8 in each M_i , $i > 1$. In particular, $\langle G, x \rangle \neq C$ for every involution x . We get

$$\Gamma_2(E_4^+, C) = 0, \quad \Gamma_2(E_4^+, M(A_4)) = 60 - \Gamma_2(E_4^+, E_8) = 48.$$

This finishes the proof. $\square$

All constants $\Gamma_i(A, B)$ have now been calculated. They are collected in Figure 1.

2.1. Random generators of arbitrary orders. According to Figure 1, there are only five orbit-nonequivalent ways to get from e to C in 3 steps. Namely,

$$\begin{aligned} \mathbf{A}_0 &= \{\{e\}, C_2, A_4, C\}, \\ \mathbf{A}_1 &= \{\{e\}, C_2, E_4^-, C\}, \\ \mathbf{A}_2 &= \{\{e\}, C_2, S_3, C\}, \\ \mathbf{A}_3 &= \{\{e\}, C_3, S_3, C\}, \\ \mathbf{A}_4 &= \{\{e\}, C_3, A_4, C\}. \end{aligned}$$

These sequences and the related constants $\Gamma_i(A, B)$ are visualized in Figure 2. Full lines correspond to involutions ($i = 2$), dotted lines to elements of order 3 ($i = 3$).

Proposition 2.3. *Let $C = M^*(2)$. Then the probability that 3 randomly chosen elements of C generate C is $p_3(C) = 955,584 \cdot 120^{-3} = 0.553$.*

Proof. By (4),

$$|\text{Gen}_3(C)| = \sum_{i=0}^4 |\mathbf{A}_{i\sim}|.$$

FIGURE 1. The constants $\Gamma_i(A, B)$ for $M^*(2)$. If A is maximal in a copy of B , then A and B are connected by a thick, straight line; else by a thin, curved line. The constants $\Gamma_2(A, B)$, $\Gamma_3(A, B)$ are located in a box on the edge connecting A and B , separated by colon.

By our previous calculation summarized in Figure 2, $|\mathbf{A}_{0\sim}| = 63 \cdot 24 \cdot (48 + 48)$, $|\mathbf{A}_{1\sim}| = 63 \cdot 24 \cdot (8 + 24)$, $|\mathbf{A}_{2\sim}| = 63 \cdot (32 + 32) \cdot (18 + 36)$, $|\mathbf{A}_{3\sim}| = 56 \cdot 36 \cdot (18 + 36)$, and $|\mathbf{A}_{4\sim}| = 56 \cdot (54 + 27) \cdot (48 + 48)$. Thus $|\text{Gen}_3(C)| = 955,584$. We are done by (1). $\square$

2.2. Random generators of given orders. The only possible types of orders for three generators in C are $(2, 2, 2)$, $(2, 2, 3)$, $(2, 3, 3)$, and $(3, 3, 3)$. The sequences of subloops corresponding to each of these types are depicted in Figure 3. We must be careful, though, since not all combinations of lines in Figure 3 correspond to

FIGURE 2. Sequences of subloops in $M^*(2)$ FIGURE 3. The shortest sequences of subloops in $M^*(2)$

sequences with correct types of orders. The possible continuations are emphasized in Figure 3.

Proposition 2.4. *Let $\mathbf{s} = (s_1, s_2, s_3)$ be a 3-tuple of integers, $s_1 \leq s_2 \leq s_3$, $C = M^*(2)$, and let $p_{\mathbf{s}}(C)$ be the probability that 3 randomly chosen elements a_1, a_2, a_3 of C generate C and $(|a_1|, |a_2|, |a_3|)$ is of type $\mathbf{s}$. Then $p_{(2,2,2)}(C) = 48,384 \cdot 120^{-3} = 0.028$, $p_{(2,2,3)}(C) = 326,592 \cdot 120^{-3} = 0.189$, $p_{(2,3,3)}(C) = 435,456 \cdot 120^{-3} = 0.252$, and $p_{(3,3,3)}(C) = 145,152 \cdot 120^{-3} = 0.084$.*

Proof. Use Figure 3 and (7). □
